NEAR-NEIGHBOR SEARCH

Slides adapted from Rajaraman and Ullman,
“Mining Massive Datasets”

<http://infolab.stanford.edu/~ullman/mmds.html>

Goals

3

- Many big-data mining problems can be expressed as finding “similar” items:
 - ▣ Pages/documents/emails with similar words, e.g., for classification, plagiarism detection.
 - ▣ Clustering of customers based on the products they buy
 - ▣ NetFlix users with similar tastes in movies, for recommendation systems.

Yemen man detained at Guantanamo Bay to be freed

A US government review panel has recommended that the Yemeni detainee at Guantanamo Bay be freed. The panel's decision is a significant step towards ending the long-standing detention of the man, who has been held at the facility since 2002. The review found that the man, identified as al-Hadi, does not meet the criteria for continued detention. The panel's decision is based on a thorough review of the evidence and the man's behavior while in custody. The man's family has expressed relief at the news of his potential release. The panel's decision is a landmark case in the history of Guantanamo Bay, as it is the first time a detainee has been recommended for release. The man's release would be a significant step towards ending the indefinite detention of prisoners at the facility. The panel's decision is based on a thorough review of the evidence and the man's behavior while in custody. The man's family has expressed relief at the news of his potential release. The panel's decision is a landmark case in the history of Guantanamo Bay, as it is the first time a detainee has been recommended for release.

Recommendation Systems

5

How can I cluster my users based on the movies they have watched?

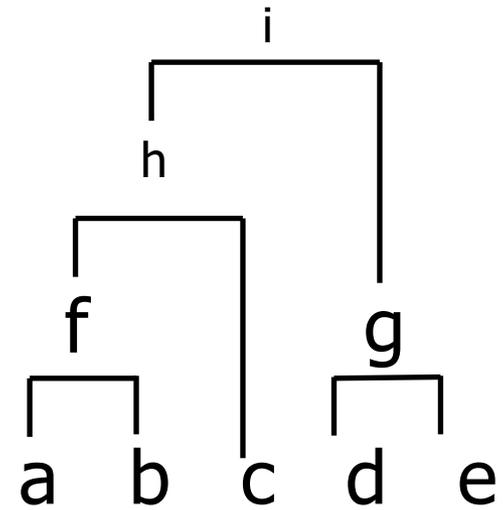

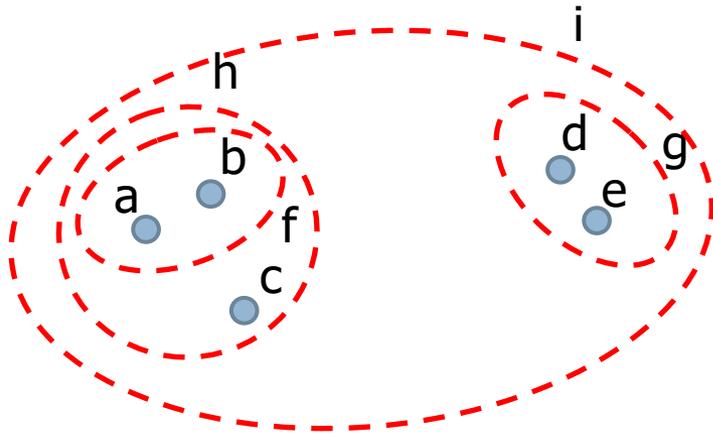

E-shop Comparison

6

How similar are they?

Hierarchical Clustering

Helpful abstraction

8

- Think of data as “Sets” of “Items”
 - News article/document/e-mail: set of tokens/strings
 - E-shop: set of products
 - Netflix user: set of movies she watched

Problems

9

- How to **construct** these sets?
- How is **similarity** between sets defined?
 - ▣ Already know the answer to this question!
- How to **efficiently** compute similarity between two sets?
 - ▣ Manage data volume, computation cost
- How to **quickly** locate similar sets on a datasets of thousands/million entries?
 - Avoid computation of similarity between sets that are not similar

Running Example: Finding Similar Documents

11

- Given a body of documents, e.g., the Web, find pairs of docs that have a lot of text in common, e.g.:
 - Mirror sites, or approximate mirrors.
 - Don't want to show both in a search.
 - Plagiarism, including large quotations.
 - Similar news articles at many news sites.
 - Reflects importance of the news item.

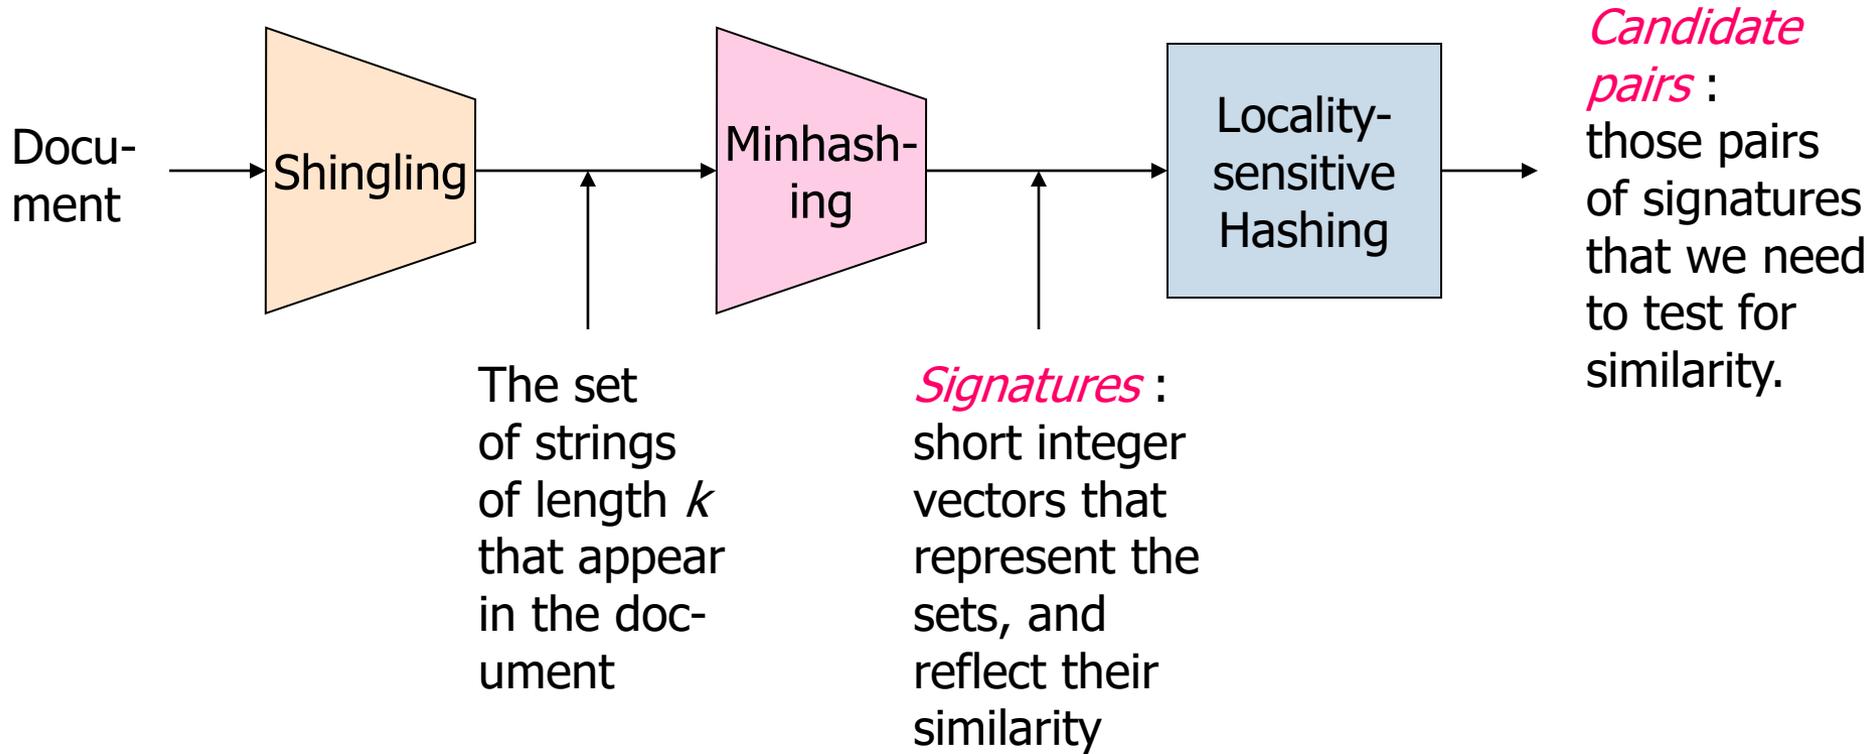

Three Essential Techniques for Similarity Testing

12

- **Shingling** : convert documents, emails, etc., to sets.
- **Minhashing** : convert large sets to short signatures, while preserving similarity.
 - ▣ Faster computation of similarity using signatures instead of the original docs
- **Locality-sensitive hashing** : focus on pairs of signatures likely to be similar.
 - ▣ Use as an index to locate (quickly) similar docs

The Big Picture

13

Comparing Documents

14

- What makes documents “similar”?
- Special cases are easy, e.g., identical documents, or one document contained character-by-character in another.
- General case, where many **small pieces** of one doc appear out of order in another, is very hard.

k-shingle: sequence of k characters in a document (q-gram)

16

Η χρησιμοποίηση δεδομένων στη λήψη σωστών, έγκυρων και έγκαιρων αποφάσεων έχει αναχθεί σε «εκ των ουκ άνευ» παράγοντα επιτυχίας για τις περισσότερες σύγχρονες επιχειρήσεις και οργανισμούς.....

H_Χρη

_Χρησ

Χρησι

ρησιμ

ησιμο

σιμοπ

ιμοπο

μοποι

Working Assumption

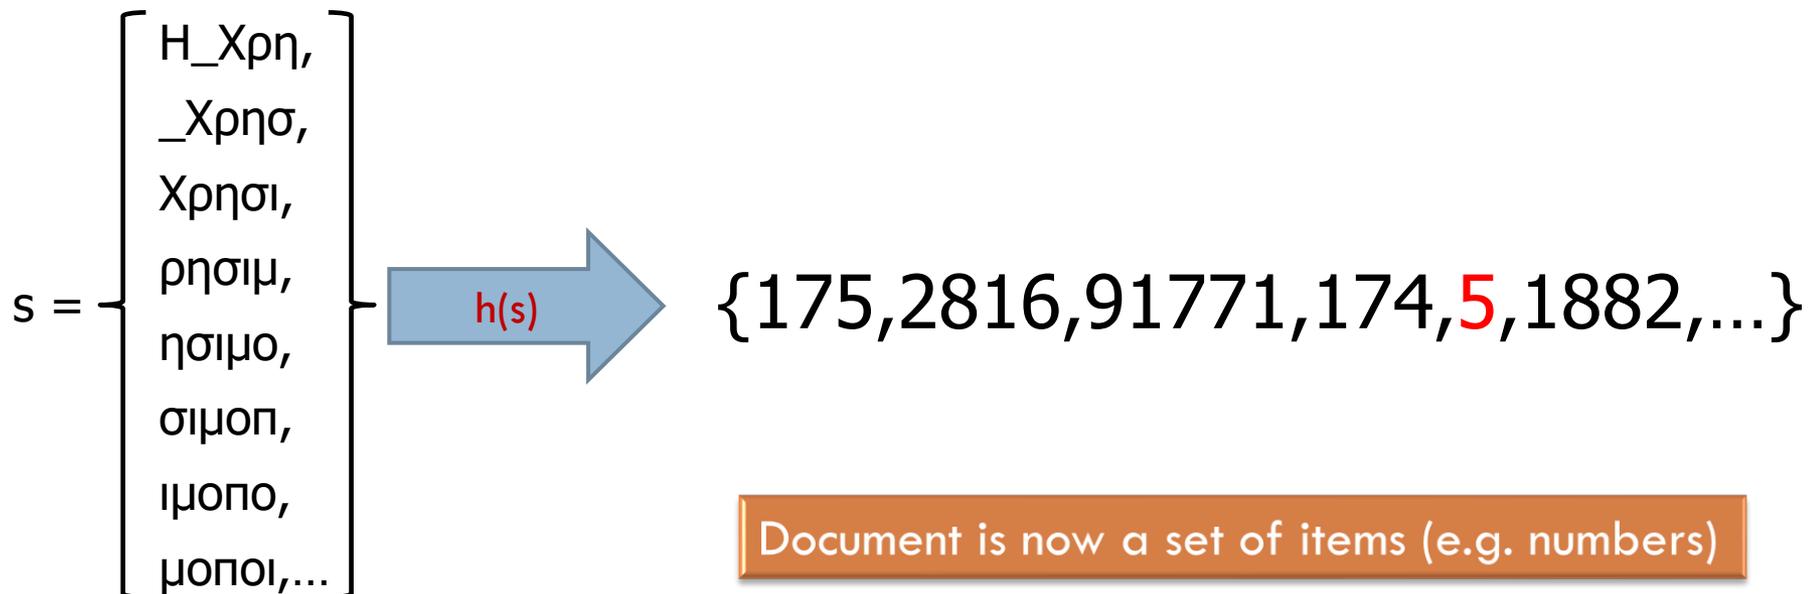

18

- Documents that have lots of shingles in common have similar text, even if the text appears in different order.
- How to select k ?
 - If k is too small, most docs will seem similar
 - If k is too large, most docs will seem dissimilar
 - $k = 5$ is OK for short documents; $k = 10$ is better for long documents.

Shingles: Compression Option

19

- Each shingle is a string of k characters
- May be easier to convert/compress them into integers via a hashing function $h()$

Note

20

- The min-hashing scheme described next can do this conversion to integers while also preserving similarity among sets (as will be explained)

MINHASHING

Data as Sparse Matrices
Jaccard Similarity Measure
Constructing Signatures

Basic Data Model: Sets

23

- Many similarity problems can be couched as finding subsets of some universal set that have large intersection.
- **Examples** include:
 1. Documents represented by their sets of shingles (or hashes of those shingles).
 2. Similar customers or products.

From Sets to Boolean Matrices

24

- **Rows** = elements of the universal set.
- **Columns** = sets.
- 1 in the row for element e and the column for set S iff e is a member of S .

In Matrix Form (won't be used in practice)

25

Documents

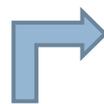

Items (shingles)

	S	T	U	V	W
1	1	1	0	1	0
2	1	0	1	1	0
3	1	0	0	1	0
4	0	1	0	0	1
5	1	0	1	0	1
6	1	1	0	1	1
7	0	1	0	1	1
8	0	1	0	1	0

This row represents a shingle (e.g. "Data_min")

In Matrix Form

This column represents document T

26

Documents

Items (shingles)

	S	T	U	V	W
1	1	1	0	1	0
2	1	0	1	1	0
3	1	0	0	1	0
4	0	1	0	0	1
5	1	0	1	0	1
6	1	1	0	1	1
7	0	1	0	1	1
8	0	1	0	1	0

In Matrix Form

27

Documents

Items (shingles)

	S	T	U	V	W
1	1	1	0	1	0
2	1	0	1	1	0
3	1	0	0	1	0
4:Data_min	0	1	0	0	1
5	1	0	1	0	1
6	1	1	0	1	1
7	0	1	0	1	1
8	0	1	0	1	0

T contains shingle "Data_min"
(assume k=8)

Documents in Matrix Form

30

- **Rows** = shingles (or hashes of shingles).
- **Columns** = documents.
- 1 in row r , column c iff document c has shingle r .
- **This matrix has a very very very very very very very very very large number of rows**
 - Expect the matrix to be sparse.

Aside

31

- We might not really represent the data by a boolean matrix.
- Sparse matrices are usually better represented by the list of places where there is a non-zero value.
 - ▣ E.g., movies rented by a customer, shingle-sets.
- But the matrix picture is conceptually useful.

Jaccard Similarity

33

- Remember: a column is the set of rows in which it has 1.
- The (Jaccard) similarity of columns $C1$ and $C2 = \text{Sim}(C1,C2) =$ the ratio of the sizes of the intersection and union of $C1$ and $C2$.
 - $\text{Sim}(C1,C2) = |C1 \cap C2| / |C1 \cup C2|.$

Example: Jaccard Similarity

34

↑
ΑΝΤΙΚΕΙΜΕΝΑ
(shingles/hash-values)
↓

	<u>C₁</u>	<u>C₂</u>		
	0	1	*	
	1	0	*	
	1	1	*	*
	0	0		
	1	1	*	*
	0	1		*
	0	0		

$$\text{Sim}(C_1, C_2) = \frac{2}{5} = 0.4 = 40\%$$

Notice that rows with 0 0 do not affect the calculated similarity

Outline: Finding Similar Columns

35

1. Compute signatures of columns = small summaries of columns.
 2. Examine pairs of signatures to find similar signatures.
 - ▣ **Essential**: similarities of signatures and columns are related.
 3. **Optional**: check that columns with similar signatures are really similar.
- These methods can produce **false negatives**, and even **false positives** (if the optional check is not made).

Warnings

36

1. Comparing all pairs of signatures may take too much time, even if not too much space.
 2. Assume 10000 documents (signatures)
 - $\#pairs = 10000 * 9999 / 2 = 49,995,000$
 - 1msec for each test
 - All comparisons will take ~ 14 hours
- A job for Locality-Sensitive Hashing.

Signatures

37

- **Key idea:** “hash” each column C to a small *signature* $Sig(C)$, such that:
 1. $Sig(C)$ is small enough that we can fit a signature in main memory for each column.
 2. $Sim(C_1, C_2)$ is approximately the same as the “similarity” of $Sig(C_1)$ and $Sig(C_2)$.

$$Sim(C_1, C_2) \approx Sim(Sig(C_1), Sig(C_2))$$

An Idea That Doesn't Work

38

- Pick 100 rows at random, and let the signature of column C be the 100 bits of C in those rows.
- Because the matrix is sparse, many columns would have 00...0 as a signature, yet have Jaccard similarity 0, because their 1's are in different rows.

Four types of rows for a pair of cols

39

- Given columns C_1 and C_2 , rows may be classified as:

	C_1	C_2	
type a:	1	1	
type b:	1	0	
type c:	0	1	
type d:	0	0	→ Jaccard score "ignores" these rows

- Notation used: $a = \#$ rows of type a , etc.
- Note $Sim(C_1, C_2) = a / (a + b + c)$.

Minhashing

40

- Imagine the rows permuted randomly.
- Define “**minhash**” function $h(C) =$ the number of the first (in the permuted order) row in which column C has 1.
- Use several (e.g., 100) independent hash functions to create a signature.

Minhashing Example

41

Permutations

S1 S2 S3 S4

1	0	0	0
1	0	1	0

Signatures

S1 S2 S3 S4

2	1	3	1
2	1	4	1
1	2	1	2

e.g. $\text{sig}(S1)=[2,2,1]$

Note signature is a **list** of minhashes (not a set)

Surprising Property

45

- The probability that $h(C_1) = h(C_2)$ is the same as $\text{Sim}(C_1, C_2)$
 - Both are $a / (a + b + c)$
- Why?
 - Look down columns C_1 and C_2 until we see a 1.
 - If it's a type- a row, then $h(C_1) = h(C_2)$. If a type- b or type- c row, then not.
 - Thus, $P[h(C_1) = h(C_2)] = a / (a + b + c)$

Estimating similarity from Signatures

46

- The *similarity of signatures* is the **fraction** of the rows in which they agree.
- Remember, each row corresponds to a permutation or “hash function.”

Signatures

	S1	S2	S3	S4
x	2	1	3	1
x	2	1	4	1
✓	1	2	1	2

Sim(S1,S3) is estimated as 1/3

Col/Col	0.50	0.75	0	0
Sig/Sig	0.33	1.00	0	0

Minhash Signatures

48

- Pick (say) 100 random permutations of the rows.
- Think of $Sig(C)$ as a column vector.
- Let $Sig(C)[i] =$
according to the i th permutation, the number of the
first row that has a 1 in column C .

Implementation – (1)

49

- Suppose 1 billion rows.
- Hard to pick a random permutation from 1...billion.
- Representing a random permutation requires 1 billion entries.
- Accessing rows in permuted order leads to thrashing.

Implementation – (2)

50

- A good approximation to permuting rows: pick “100” hash functions.
- For each column c and each hash function h_i , keep a “slot” $M(i, c)$ for that minhash value.

Implementation – (3)

51

for each row r

for each column c

if c has 1 in row r

for each hash function h_i **do**

if $h_i(r)$ is a smaller value than
 $M(i, c)$ **then**

$M(i, c) := h_i(r);$

Example

52

- Assume 5 rows and $h_1(r) = (2r+1) \bmod 5$
 - ▣ $h_1(r)$ implies a “random” permutation of the rows
- $\text{Sig}(C1) = 2$ (first “1” in the order implied by $h_1(r)$)
- To compute $\text{Sig}(C1)$ we evaluate $h_1(r)$ for the rows that contain “1” and keep the **minimum** value

	$h_1(r)$	Row	C_1	C_2
	3	1	1	0
	0	2	0	1
→	2	3	1	1
	4	4	1	0
	1	5	0	1

Note that "row r" represents an item stored in the set, thus we are essentially hashing the set elements

Example

54

- Assume 5 rows and $h_1(r) = (2r+1) \bmod 5$
 - ▣ $h_1(r)$ implies a "random" permutation of the rows
- $\text{Sig}(C_1) = 2$ (first "1" in the order implied by $h_1(r)$)
- To compute $\text{Sig}(C_1)$ we evaluate $h_1(r)$ for the rows that contain "1" and keep the **minimum** value

minimum hash value of rows with "1" denotes position of first "1"

$h_1(r)$	Row	C_1	C_2
3	1	1	0
0	2	0	1
2	3	1	1
4	4	1	0
1	5	0	1

$$\text{Sig}(C_1) = 2$$
$$\text{Sig}(C_2) = 0$$

Example with 3 hash functions

55

Row	C_1	C_2
1	1	0
2	0	1
3	1	1
4	1	0
5	0	1

$$h(r) = r \bmod 5$$

$$g(r) = (2r+1) \bmod 5$$

$$z(r) = (3r+1) \bmod 5$$

	Sig1	Sig2
$h(1) = 1$	1	-
$g(1) = 3$	3	-
$z(1) = 4$	4	-
$h(2) = 2$	1	2
$g(2) = 0$	3	0
$z(2) = 2$	4	2
$h(3) = 3$	1	2
$g(3) = 2$	2	0
$z(3) = 0$	0	0
$h(4) = 4$	1	2
$g(4) = 4$	2	0
$z(4) = 3$	0	0
$h(5) = 0$	1	0
$g(5) = 1$	2	0
$z(5) = 1$	0	0

Final outcome

56

Row	C_1	C_2
1	1	0
2	0	1
3	1	1
4	1	0
5	0	1

Signatures:	C_1	C_2	
	1	0	X
	2	0	X
	0	0	✓

Our estimate: $1/3$

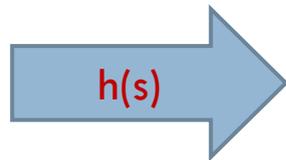

Actual similarity: $1/5$

Minhash on Shingles

57

- Hash each shingle into an integer
- Keep minimum value
 - ▣ Done!

H_Χρη
_Χρησ
Χρησι
ρησιμ
ησιμο
σιμοπ
ιμοπο
μοποι

{175,2816,91771,174,5,1882,...}

Think of $h(s)$ as a random permutation of the shingles

In other words....

58

- Have two sets A, B.
- Reorder items on both sets based on a hash function.
- Keep the minimum value.
- Recall that the hash function “randomly” shuffles the items in both sets.
- Probability of the min hashes being equal = probability of the random permutation imposed by the hash returns the same item at the top = intersection over union = jaccard similarity.

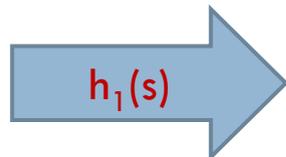

Use multiple hash functions to obtain a signature

59

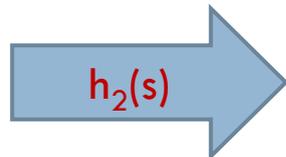

- E.g. apply a family of (string) hash functions

Doc:

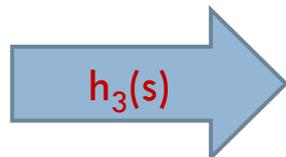

H_Χρη
_Χρησ
Χρησι
ρησιμ
ησιμο
σιμοπ
ιμοπο
μοποι

{175,2816,91771,174,**5**,1882,...}

{**25**,216,151,317,52,84,...}

{6521,635,9002,**412**,884,...}

Minhash(doc)=[5,25,412]

Implementation – (4)

60

- If data is stored row-by-row, then only one pass is needed.
- If data is stored column-by-column
 - ▣ E.g., data is a sequence of documents represent it by (row-column) pairs and sort once by row.
 - ▣ Saves cost of computing $h_i(r)$ many times.

Additional Examples: Uses of Minhashing

61

- **Common pattern:** looking for sets with a relatively large intersection.
- Represent a customer, e.g., of Netflix, by the set of movies they rented.
- Similar customers have a relatively large fraction of their choices in common.

LOCALITY-SENSITIVE HASHING

Focusing on Similar Minhash Signatures

Other Applications Will Follow

Finding Similar Pairs

64

- Suppose we have, in main memory, data representing a large number of objects.
 - ▣ May be the objects themselves.
 - ▣ May be signatures as in minhashing.
- We want to compare each to each, finding those pairs that are sufficiently similar.

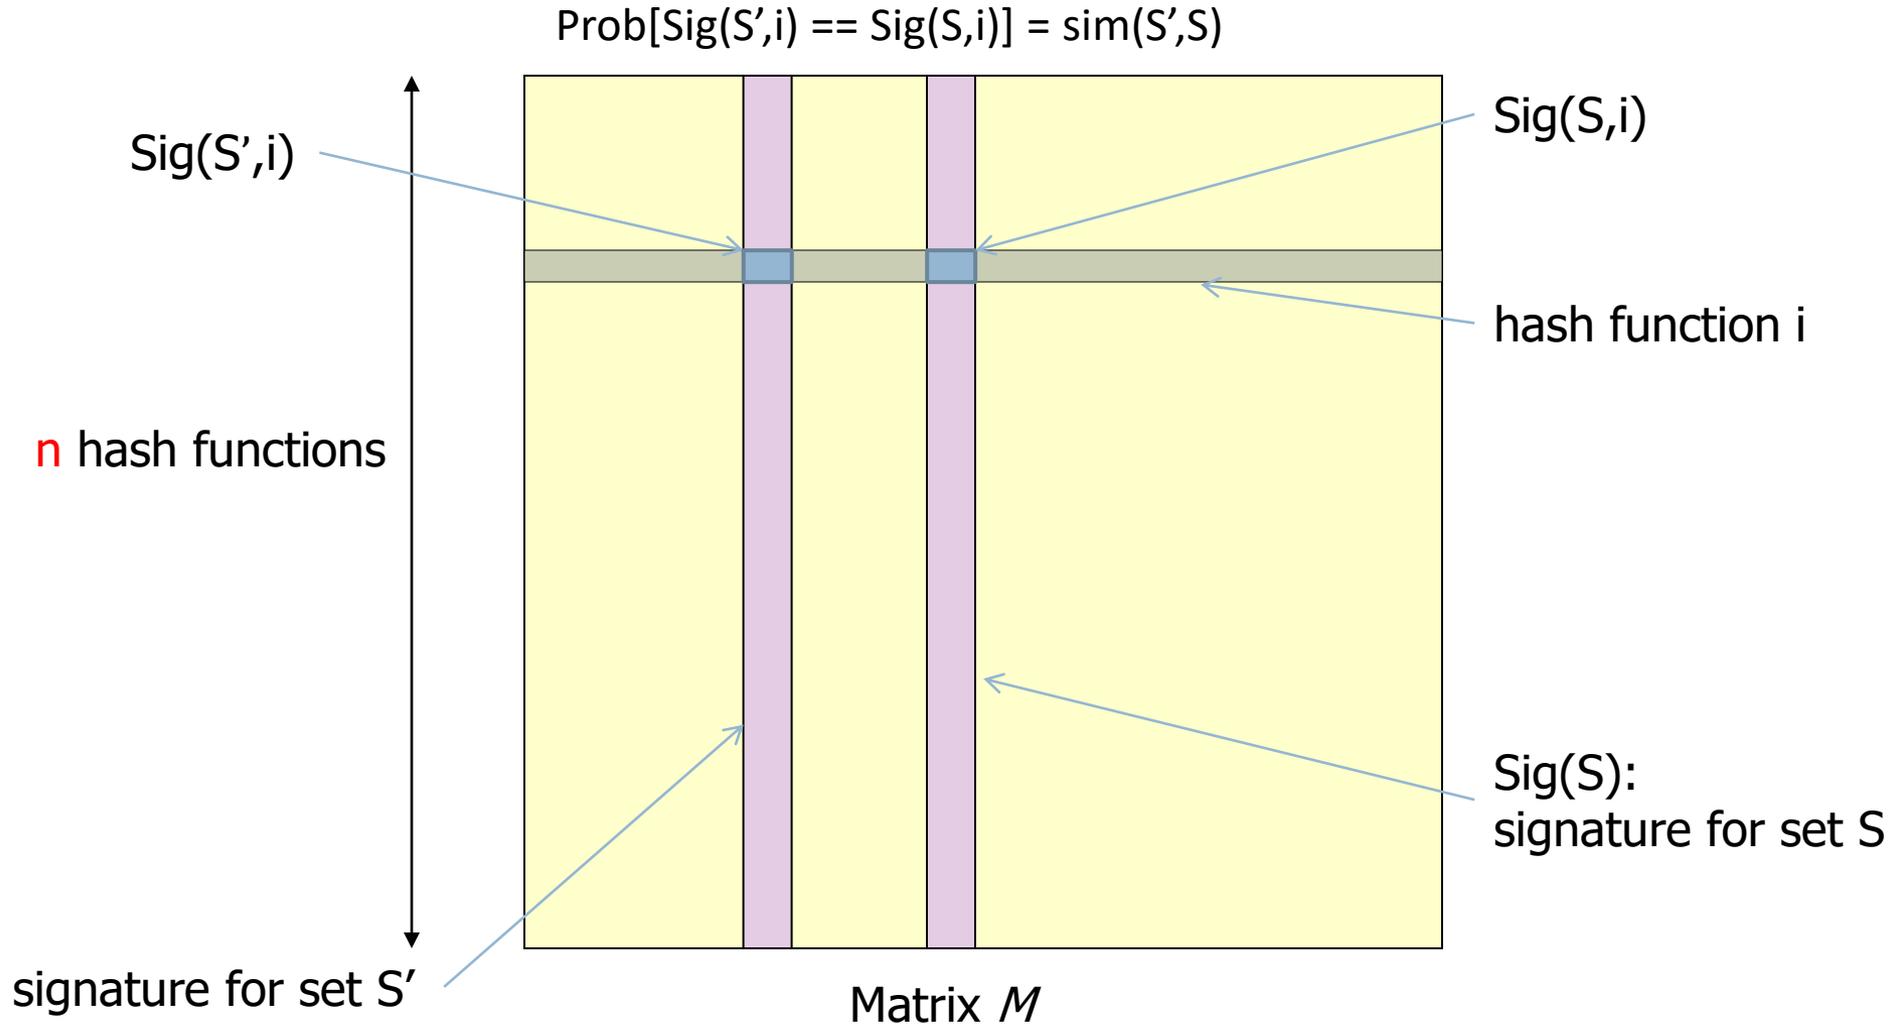

Candidate Generation From Minhash Signatures

65

- Pick a similarity threshold $s < 1$
- A pair of columns c and d is a *candidate pair* if their signatures agree in at least fraction s of the rows
 - i.e., $M(i, c) = M(i, d)$ for at least fraction s values of i

Signature matrix reminder

66

Checking All Pairs is Hard

67

- While the signatures of all columns may fit in main memory, comparing the signatures of all pairs of columns is quadratic in the number of columns.
- **Example:** 10^6 columns implies $5 \cdot 10^{11}$ comparisons.
- At 1 microsecond/comparison: 6 days.

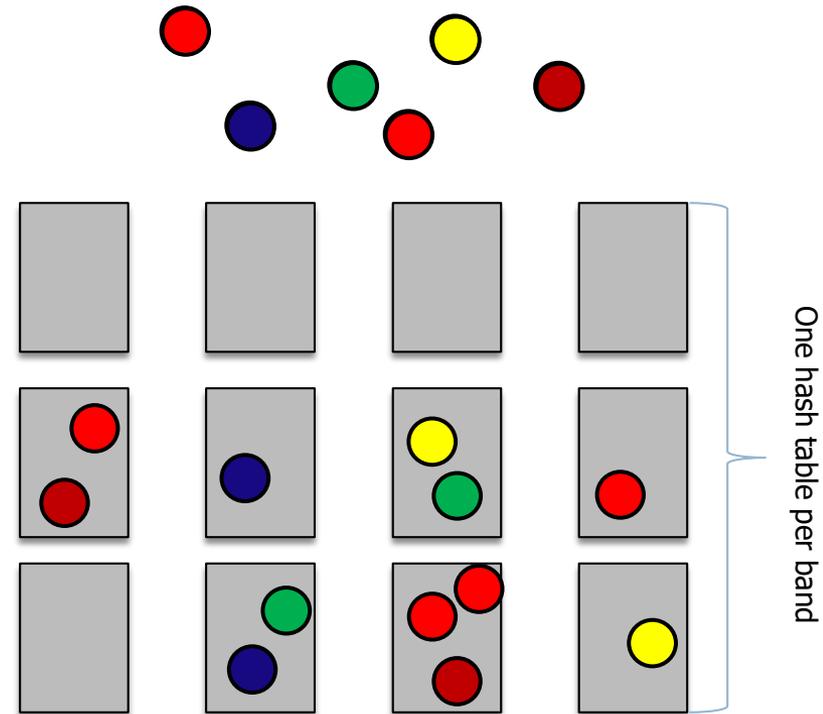

Locality-Sensitive Hashing

68

Overview

- Partition columns of signature matrix into bands (mini signatures)
- Arrange that (only) similar bands are likely to hash to the same bucket
- Candidate pairs are those that hash (at least once) to the same bucket

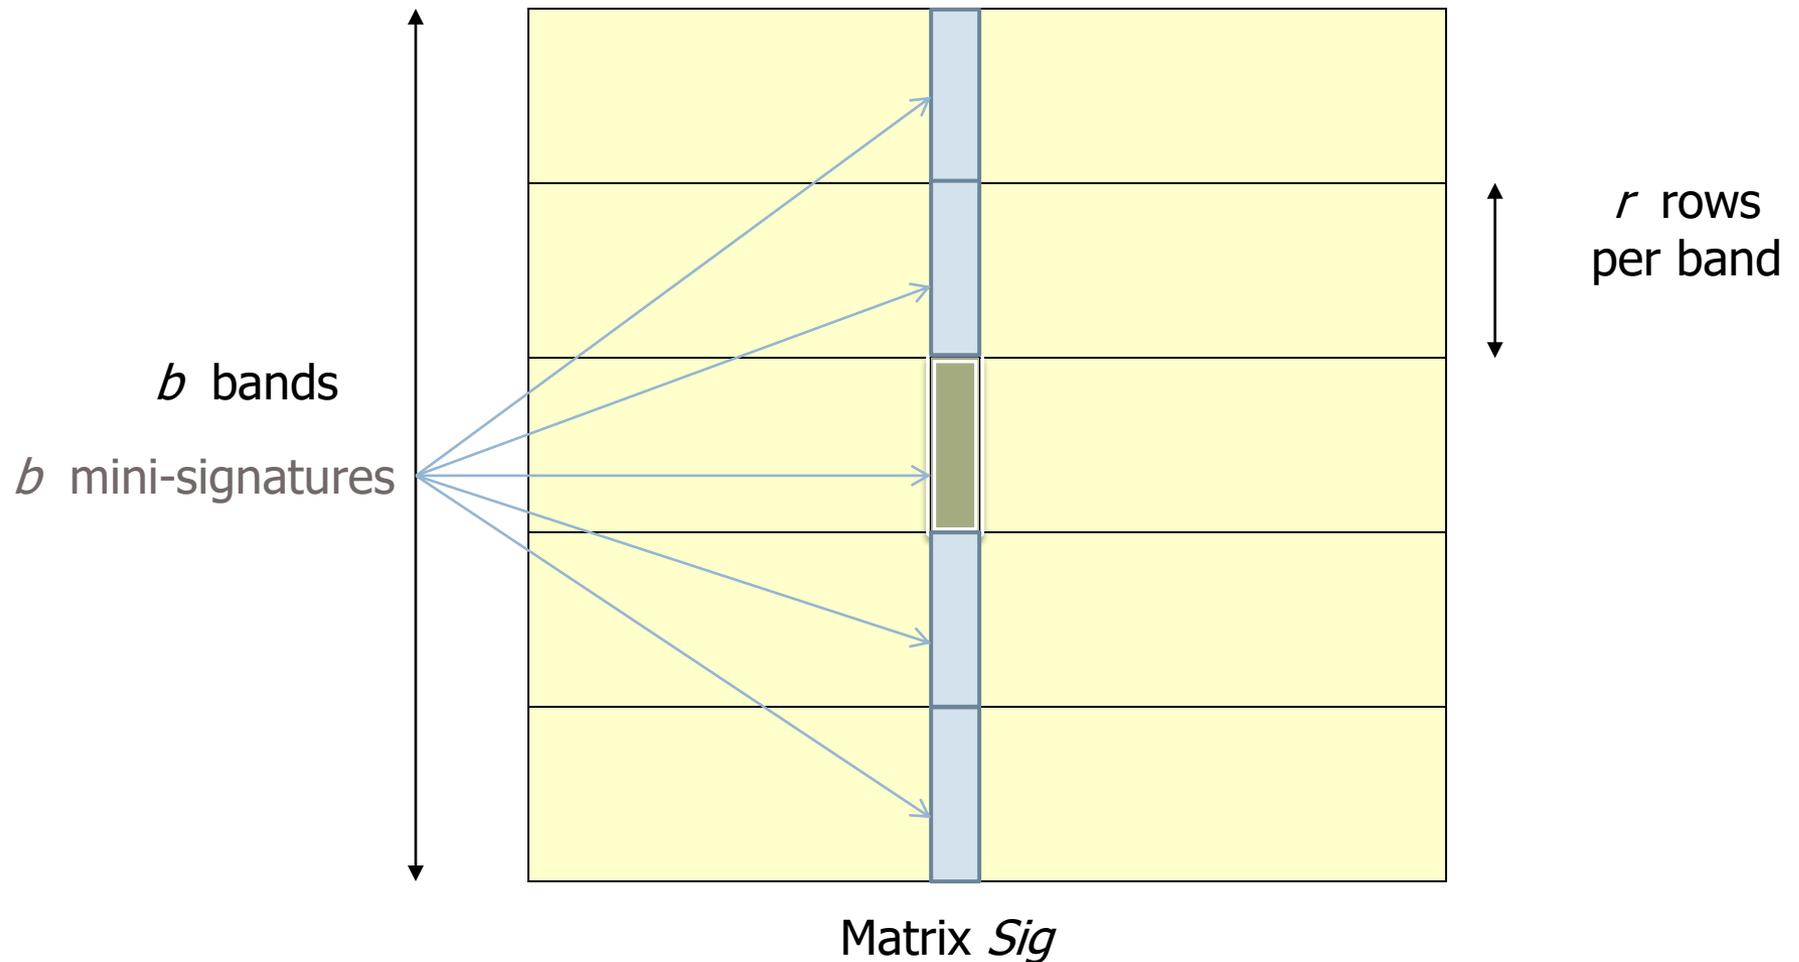

Visualization

Partitioning into bands

69

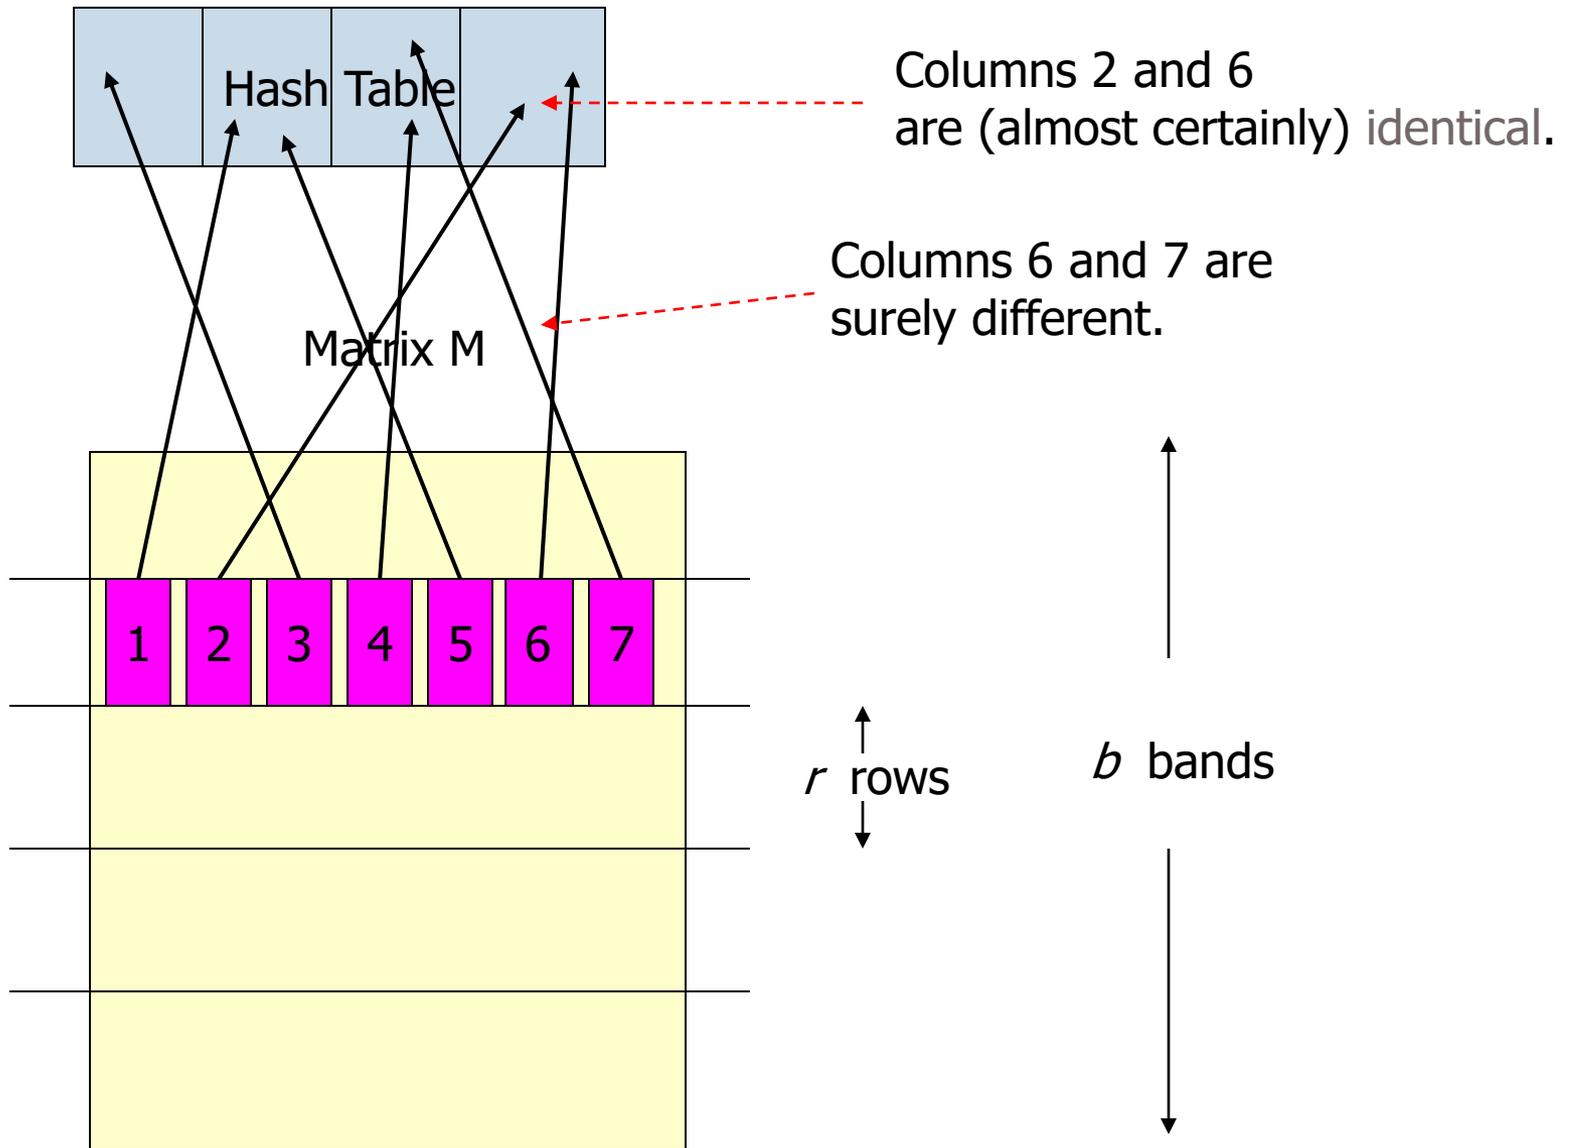

$n = b * r$ hash functions

Partition into Bands – (2)

71

- **Divide** matrix M into b bands of r rows.
- For each band, hash its portion of each column to a hash table with k buckets.
- **Candidate** column pairs are those that hash to the same bucket for ≥ 1 band.
- Tune b and r to catch most similar pairs, but few nonsimilar pairs.

Simplifying Assumption

74

- There are enough buckets that columns are unlikely to hash to the same bucket unless they are **identical** in a particular band.
- Hereafter, we assume that “same bucket” means “identical in that band.”

Example: Effect of Bands

75

- Suppose 100,000 columns.
- Signatures of 100 integers.
- Therefore, signatures take 40Mb.
- Want all 80%-similar pairs.
- 4,999,950,000 pairs of signatures can take a while to compare.
- Choose 20 bands of 5 integers/band.

Suppose S1, S2 are 80% Similar

$$\text{Prob}[\text{Sig}(S,i) == \text{Sig}(S',i)] = \text{sim}(S,S')=0,8$$

76

- We want all 80%-similar pairs. Choose 20 bands of 5 integers/band.
- Probability S1, S2 **identical** in one particular band:
 - ▣ $(0.8)^5 = 0.328$ (mini-signatures agree in all 5 digits)
- Probability S1, S2 **are not similar** in any of the 20 bands:
 - ▣ $(1-0.328)^{20} = 0.00035$
 - i.e., about 1/3000-th of the 80%-similar column pairs are **false negatives**.
- Probability S1, S2 are similar in at least one of the 20 bands:
 - ▣ $1-0.00035 = 0.99965$
 - ▣ So with 99.965% probability we will get them!

Suppose S1, S2 Only 20% Similar (we do not want them in the result)

77

- Probability S1, S2 identical in any one particular band:
 $(0.2)^5 = 0.00032$
- Probability S1, S2 identical in ≥ 1 of 20 bands:
 $\leq 1 - (1 - 0.00032)^{20} = 0.6\%$
 - ▣ So with probability 0.6% we will get them (false positives)
 - ▣ But will can still discard them if we make the optional test in the end using the real sets
- False positives much lower for similarities $\ll 20\%$.
 - ▣ It becomes very unlikely that we will get really dissimilar columns via LSH

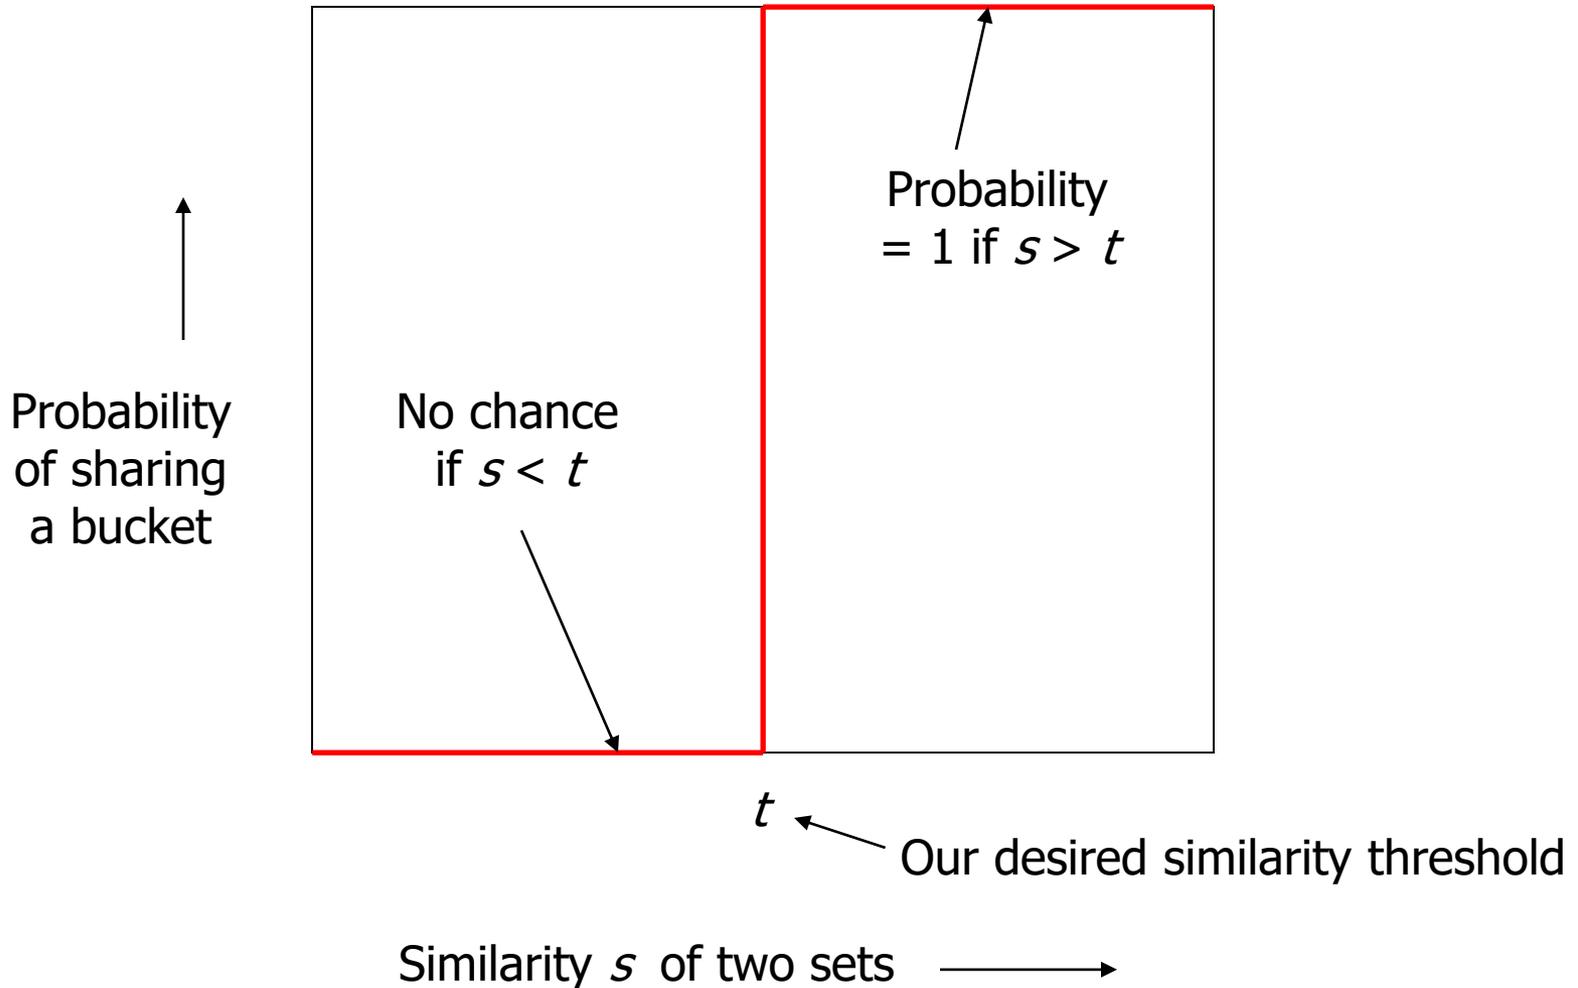

LSH Involves a Tradeoff

78

- Pick the number of minhashes, the number of bands, and the number of rows per band to balance false positives/negatives.
- **Example:** if we had fewer than 20 bands (increased size of mini signatures), the number of false positives would go down, but the number of false negatives would go up.

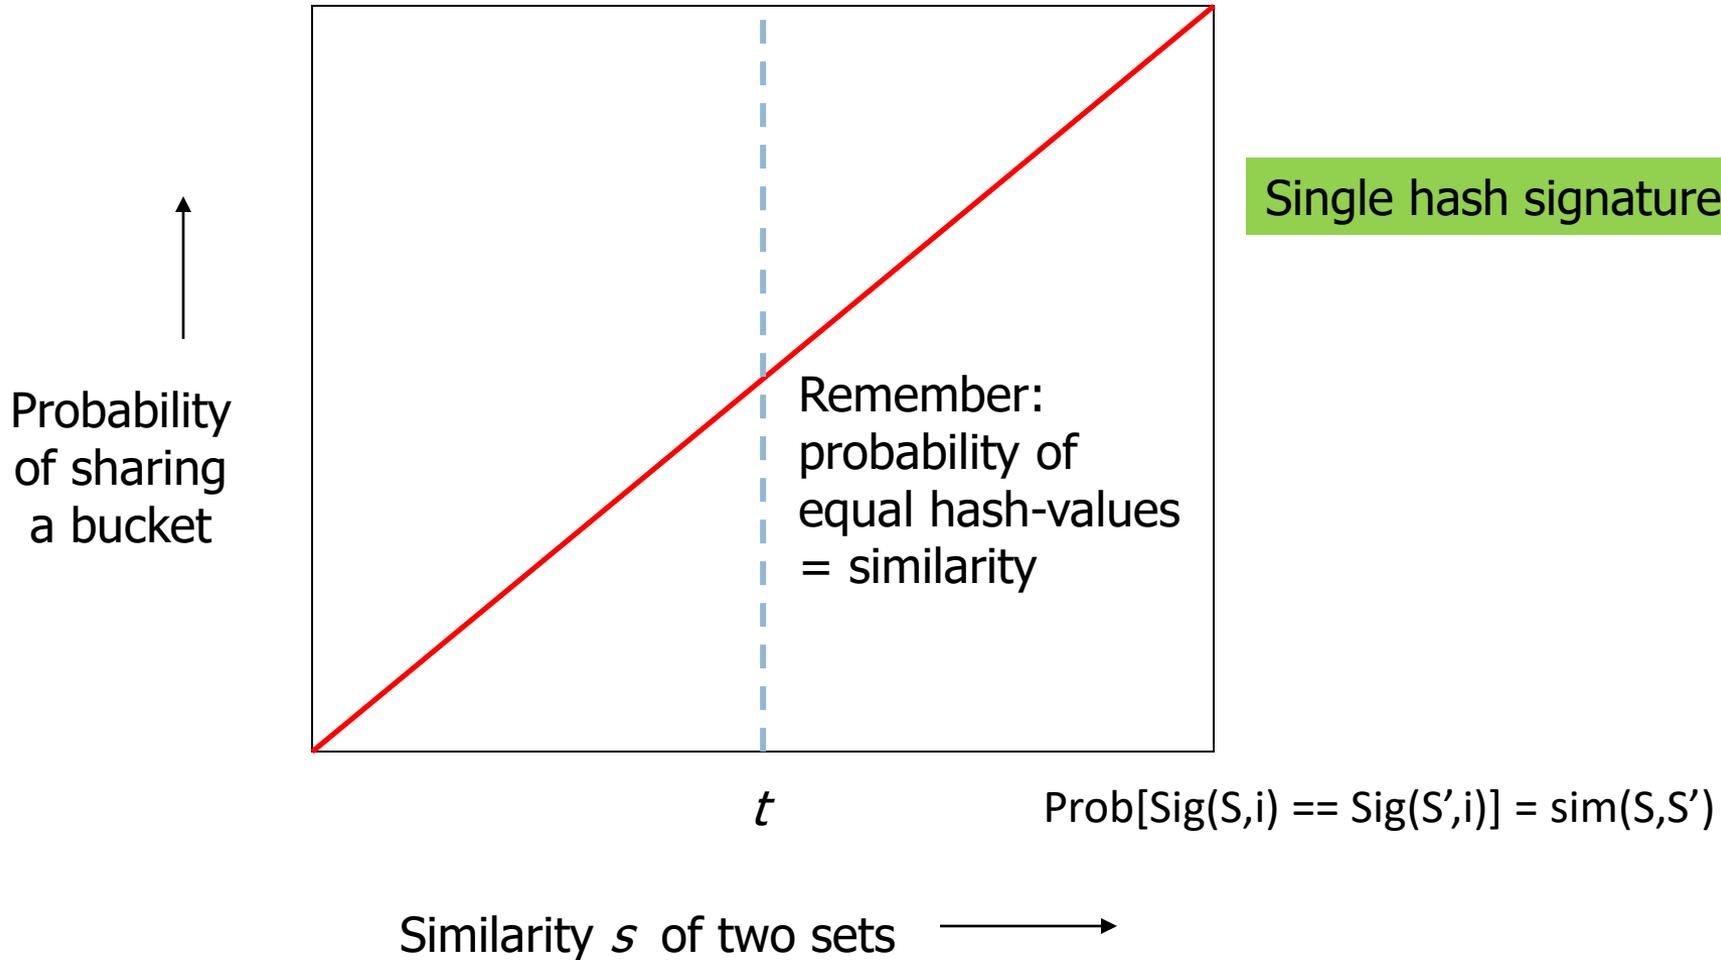

Analysis of LSH – What We Want

79

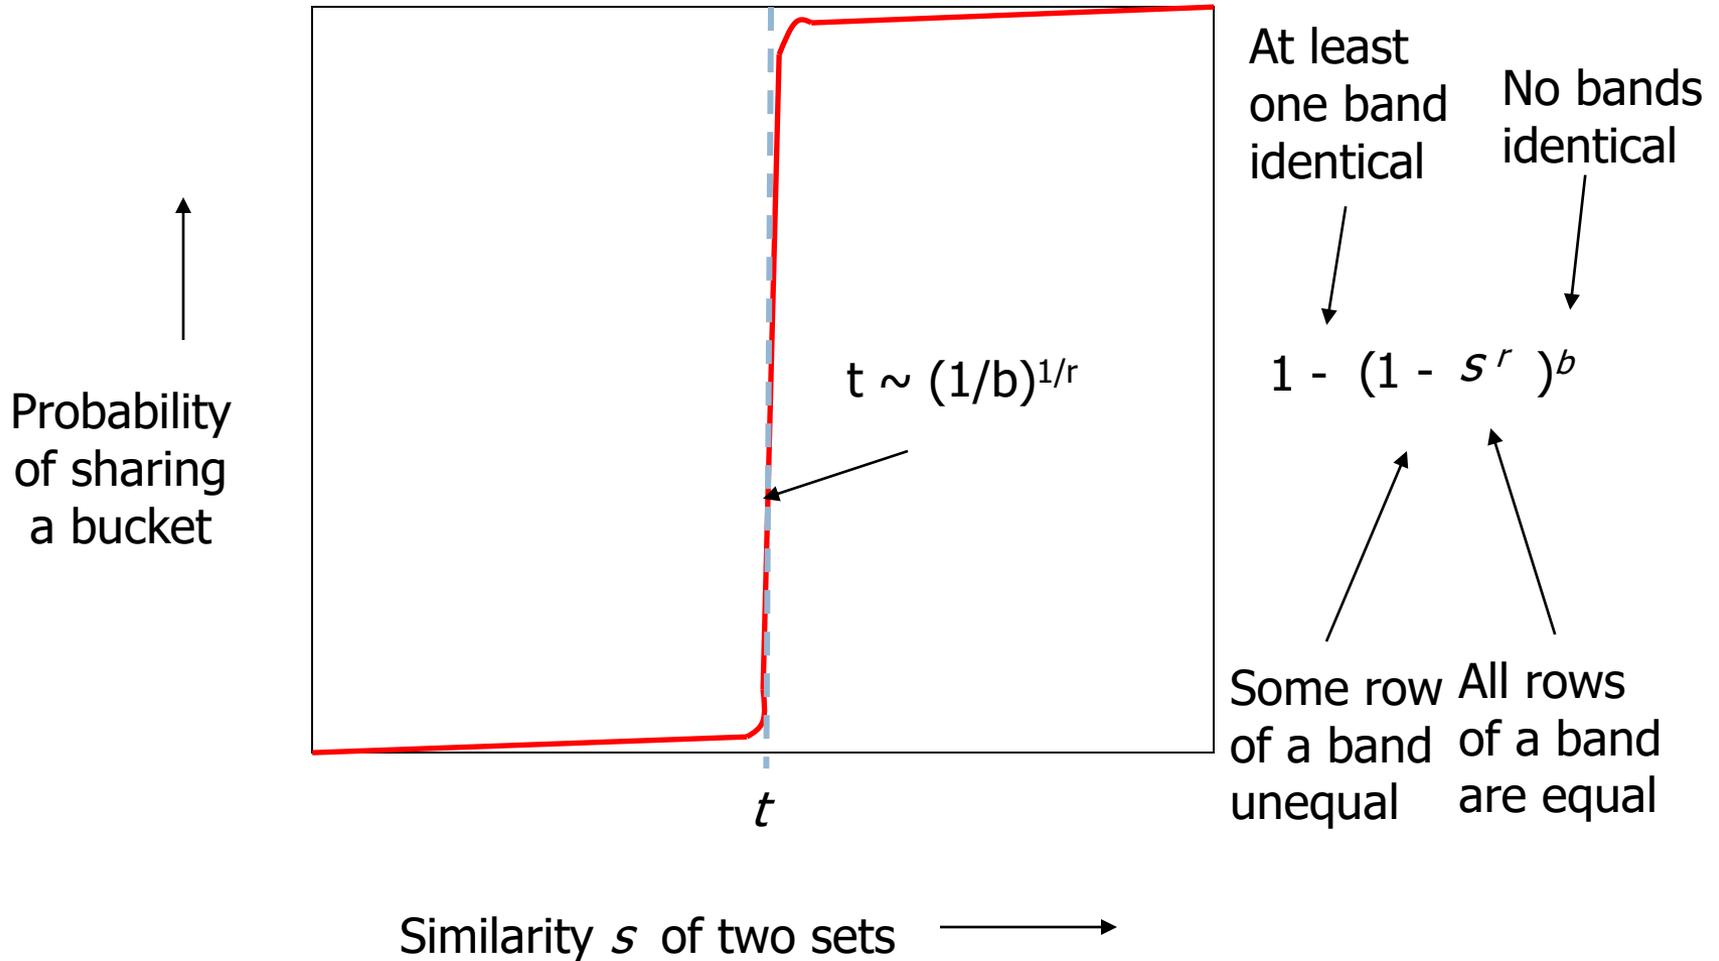

What One Band of One Row Gives You

80

What b Bands of r Rows Gives You

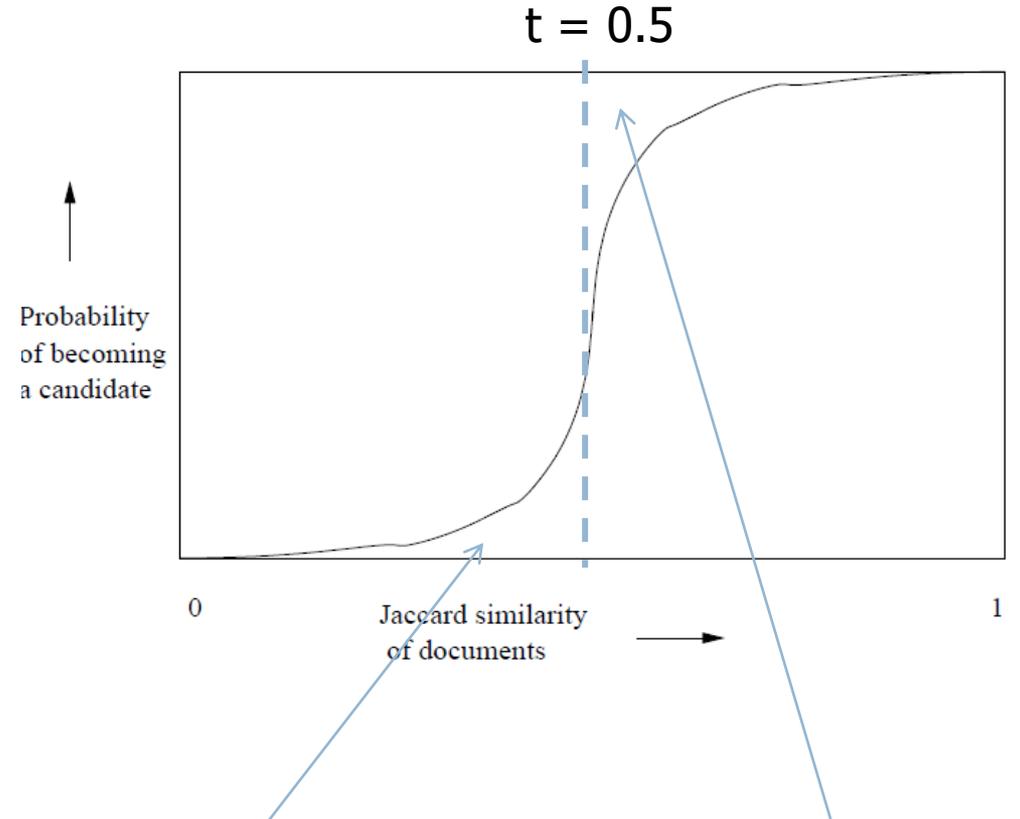

81

Example: $b = 20; r = 5$

82

s	$1-(1-s^r)^b$
.2	.006
.3	.047
.4	.186
.5	.470
.6	.802
.7	.975
.8	.9996

This part of the area below the curve = probability of false positives

This part of the area above the curve = probability of false negatives

LSH Summary (Document Similarity)

83

- Tune to get almost all pairs with similar signatures but eliminate most pairs that do not have similar signatures.
- Check in main memory that candidate pairs really do have similar signatures.
- **Optional:** In another pass through the data, check that the remaining candidate pairs really represent similar *sets*.
 - ▣ This way we avoid false positives
