

Regression Analysis Simple Linear Regression and LS	Regression Analysis Interpretation of Regression Coefficients
Regression Equation and LS – III	Interpretation of the Slope and the Intercept
 Differential calculus is used to obtain the coefficient estimators b₀ and b₁ that minimize SSE. b₁ = \frac{\sum_{i=1}^n (x_i - \overline{x})(y_i - \overline{y})}{\sum_{i=1}^n (x_i - \overline{x})^2} = \frac{\text{Cov}(x, y)}{s_x^2} = r_{xy} \frac{s_y}{s_x} b₀ = \overline{y} - b_1 \overline{x} The (sample) regression line always goes through the means \overline{x}, \overline{y}. 	 b₀ is the estimated average value of y when the value of x is zero (if x = 0 is in the range of observed x values) b₁ is the estimated change in the average value of y as a result of a one-unit change in x : Δy = b₁Δx so b₁ = Δy/Δx

Square Feet

n Analysis Prediction

Prediction – IV

• *Goal*: Form intervals around *Y* to express uncertainty about the value of *Y*₀ for a given *X*₀

Prediction - VI

• Confidence interval estimate for an actual observed value of *y* given a particular *x*₀

$$\hat{y}_0 \pm t_{n-2,\alpha/2} \cdot s_e \sqrt{1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2}}$$

- The extra term (1) comes in because the regression is used to estimate the value of one value of y (at given x₀)
- Confidence Interval Estimate for $E(Y_0|X_0)$: Find the 95% confidence interval for the mean price of 2,000 square-foot houses
 - ▶ Predicted Price $\hat{y} = 317.85(\$1,000s)$ so

$$\hat{y}_0 \pm t_{n-2,\alpha/2} \cdot s_e \sqrt{\frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2}} = 317.84 \pm 37.15$$

Regression Anarys

Prediction – V

• Confidence interval estimate for the expected value of *y* given a particular *x*₀

$$\hat{y}_0 \pm t_{n-2,\alpha/2} \cdot s_e \sqrt{\frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2}}$$

Prediction

- Notice that the formula involves the term $(x_0 \bar{x})^2$ so the size of interval varies according to the distance x_0 is from the mean, \bar{x} .
- Technically this formula is used for infinitely large populations. However, we can interpret our problem as attempting to determine the average selling price of **all** houses, all with 1,500 square feet.

Prediction

ヘロト ヘヨト ヘヨト

22/30

Prediction – VII

P. Konstantinou (AUEB)

- The confidence interval endpoints are 280.66 and 354.90, or from \$280,660 to \$354,900
- Confidence Interval Estimate for \hat{Y}_0 : Find the 95% confidence interval for an individual house with 2,000 square feet
 - ▶ Predicted Price $\hat{y} = 317.85(\$1,000s)$ so

$$\hat{y}_0 \pm t_{n-2,\alpha/2} \cdot s_e \sqrt{1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2}} = 317.84 \pm 102.28$$

The confidence interval endpoints are 215.50 and 420.07, or from \$215,500 to \$420,070.
